Repair of Ventral Hernia Locating on the Abdominal Border

Hiroshi Hirukawa
Department of Surgery, Tachikawa General Hospital, Japan

Purpose: To assess the outcomes of our surgical approach to the incisional hernia of the abdominal border.

Methods and patients: A defect closure (IPOM plus) was performed in the laparoscopic approach. We employed large mesh at least 5-7cm extending from the edge of incisional hernia in all direction. The mesh extended deep under the diaphragm for subxiphoidal and subcostal hernia and was fixed. A total of 19 consecutive incisional hernia of the abdominal border were operated in the last 5 years in Tachikawa General Hospital, Department of Surgery. Operative procedure, mesh selection, morbidity, mortality and recurrence rate were evaluated.

Results: The hernias were located in subxiphoidal (n=3), subcostal (n=9), suprapubic (n=5), right suprainguinal (n=1), and left suprailiac (n=1). Thirteen patients underwent laparoscopic hernia repair, but 2 patients required open procedures because of intra-abdominal dense adhesion. IPOM plus were performed in 10 patients with subxiphoidal (n=3), subcostal (n=2), and suprapubic hernia (n=5). In other 5 patients, Ponsky-Lin technique (n=3), Rives Stoppa technique (n=1), or transverse abdominis muscle (n=1) were performed. After surgery, seroma was developed in 2 patients (10.5%). However, no mesh infection, no mortality, nor morbidity was observed during the follow up period of 750 days (ranging 40-1847 days). The recurrence was observed in 2 (10.5%) patients with subcostal hernias which was repaired by light weight mesh.

Conclusion: IPOM plus using large mesh is a safe and effective for ventral hernia repair located on the abdominal border. The use of heavy weight mesh would be recommended for large hernia.
Laparoscopic repair with transcutaneous closure of defect for large midline incisional hernia extended to bilateral subcostal margins: report of a case

Laparoscopic repair for incisional hernia extended to subcostal margin may be considered difficult, because it is anatomically adjacent to both rib and diaphragm. We herein report a case of such patient for whom laparoscopic repair using mesh with transcutaneous closure of defect was successfully carried out.

A 65-year-old woman was diagnosed with symptomatic incisional hernia after open cholecystectomy. The physical examination revealed a 20 × 15 cm bulging mass that extended to the bilateral subcostal margin. The computed tomography visualized a 14 × 10 cm fascial defect, and that was confirmed intraoperatively with direct measurement.

The patient was placed in a supine position, and four trocars were introduced (two 5-mm and two 12-mm trocars). Following adhesiolysis, a monofilament thread for suture passage device was used to reduce the hernia contents. The defect was transcutaneously fashioned from the left to the right side of the defect using a suture passage device. The interval of each thread was 1 to 1.5 cm. All sutures were sequentially tied and the knots were buried subcutaneously.

A 25 × 20 cm composite multifilament polyester mesh was selected in order to obtain a 5 cm overlap. Mesh fixation was performed by absorbable tacks with additional full-thickness sutures using non-absorbable monofilament. The postoperative course was uneventful and the patient was discharged home.

Follow-up evaluation was done at 1, 3, 6, and 12 months. Computed tomography was performed at 3 and 12 months. There were no clinically or radiographically significant complications.

Our proposed surgical technique is safe and suitable for large incisional hernia extended to bilateral subcostal margins.

Laparoscopic IPOM plus- better method for lateral incisional hernia repair

Sameer Ashok Rege, Yogesh Takalkar, Shrinivas Surpam, Abhay Narendra Dalvi
Department of Surgery, Seth GS Medical College & KEM Hospital, India

Lateral incisional hernia repair poses a challenge to any surgeon. The repair is not only the reduction of contents and closure of the defect, but challenge to deal with the bulge following the weakness of the muscles. In open surgery, it is very difficult to place a sublay or inlay mesh due to proximity of the bony prominences; nerves in the same plane and have a appropriate closure of the defect.

We operated 176 patients with lateral incisional hernia. There were 63 males. Age range was between 22 to 76 years. Primary surgery of open appendicectomy was done in 62 patients, LSCS and other gynecological procedures in 87 patients. 3 patients had hernia following iliac crest graft, 5 urology surgery, one following donor heptectomy.

All surgery were done in general anaesthesia. Port placement were decided as per the defect. Careful adhesiolysis was done following which the defect was sutured with intracorporeal continuous nonabsorbable sutures. Dual mesh was used to reinforce the hernia, the size calculated with 3 cms on either side of defect in an nonapproximated defect. External compression was given to the patient with appropriate counselling. Followup of month, six months and an year was kept which showed much better cosmetically results. There were no wound infection, recurrence, except of 2 patients forming seroma which were treated conservatively.

Minimally Invasive Approach to Supra-pubic and Non-Midline Lower Abdominal Incisional Hernia an Extended Indication of TAPE Technique

Joe KM Fan, Dominic CC Foo, Jeremy Yip, KK Ng, Oswens SH Lo, Rockson Wei, WL Law
Department of Surgery, Queen Mary Hospital, The University of Hong Kong, Hong Kong

Objective: TAPE technique has been described for the repair of supra-pubic midline incisional hernia with satisfactory outcome. Our aim is to study the feasibility and safety of repairing non-midline lower abdominal hernia as an extended indication for TAPE technique.

Method: Patients with IPOM ventral hernia repair in all affiliated Hospitals of the University of Hong Kong were reviewed. Prospectively collected data were retrospectively analyzed.

Surgical Technique: Peritoneal incision was created just below the defect with pre-peritoneal dissection. Non-adhesive mesh then placed partial intra-peritoneally to cover the defect, and partially cover the whole extra-peritoneal space prepared. Meshes were fixed by tackers for intra-peritoneal part, most inferior fixation points were at peritoneal incision line. Extra-peritoneal part of meshes covered up by the peritoneal flap. Fixation of this part of the meshes were facilitated by the peritoneal flap and subsequent fibrosis and adhesion to the extra-peritoneal structures.

Results: From 1.2008 to 6.2016, among 123 patients reviewed, 3 with lateral lower abdominal hernia requiring extended TAPE repair were included for the analysis with 1 right lower paramedian and 2 post-TRAM flap donor site incisional hernia. All are female patients with mean age of 49.7 years old, mean size of defect was 123.3 cm² and mean follow-up time of 22.2 months. All patient recovered uneventfully and no morbidity or recurrence noted.

Conclusion: Repair of lateral lower abdominal incisional hernia with this novel modified technique is safe and feasible. A larger case series and longer follow-up is required for validation.
Mesh fixation with glue versus suture for recurrence and pain in Lichtenstein inguinal hernioplasty

Ping Sun, Xiang Cheng, Zifang Song, Chen Zhang, Ming Li, Shaobo Hu, Qichang Zheng
Hepatobiliary and Hernia Department, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, China

Objectives: To determine whether glue can reduce postoperative chronic pain, without increasing the recurrence rate, compared with sutures for mesh fixation in Lichtenstein hernia repair.

Methods: We searched The Cochrane Central Register of Controlled Trials, MEDLINE, EMBASE, Web of Science with no language restrictions. Reference lists of identified papers were also checked. All randomised and quasi-randomised controlled trials were considered for inclusion.

Results: Twelve trials with a total of 1987 patients were included in this review. The overall postoperative chronic pain in the glue group was reduced by 37% (OR 0.63, 95% CI: 0.44 to 0.91; low quality of the evidence) compared with the suture group. Hernia recurrence was similar between the two groups (OR 1.44, 95% CI: 0.63 to 3.28; low quality of the evidence). Fixation with glue was superior to suture regarding duration of the operation (SMD -0.37, 95% CI: -0.52 to -0.23; moderate quality of the evidence); haematoma (OR 0.52, 95% CI: 0.31 to 0.86; moderate quality of the evidence); and recovery time to daily activities (SMD -0.81, 95% CI: -1.05 to -0.58; moderate quality of the evidence). There were no significant differences between the two groups regarding the adverse events, superficial wound infection, mesh/V deep infection, seroma, persisting numbness, postoperative length of stay.

Conclusions: Glue may reduce postoperative chronic pain and not simultaneously increase the recurrence rate, compared with sutures for mesh fixation in Lichtenstein hernia repair.
